Learning relative attributes: age

Figure: Age: a relative attribute estimated from paired comparisons (Fu-Hospedales-Xiang-Gong-Y. *ECCV*, 2014)

Random Graphs

Game Theory 00000000000

Netflix Customer-Product Rating

Example (Netflix Customer-Product Rating)

- 480189-by-17770 customer-product 5-star rating matrix X with X_{ij} = {1,...,5}
- X contains 98.82% missing values

However,

- pairwise comparison graph G = (V, E) is very dense!
- only 0.22% edges are missed, almost a complete graph
- rank aggregation may be carried out without estimating missing values
- imbalanced: number of raters on $e \in E$ varies

Random Graphs

Game Theory 00000000000

Drug Sensitivity Ranking

Example (Drug Sensitivity Data)

- 300 drugs
- \blacksquare 940 cell lines, with ≈ 1000 genetic features
- sensitivity measurements in terms of IC50 and AUC
- heterogeneous missing values

However,

- every two drug d₁ and d₂ has been tested at least in one cell line, hence comparable (which is more sensitive)
- complete graph of paired comparisons: G = (V, E)
- imbalanced: number of raters on $e \in E$ varies

Paired comparison data on graphs

Graph G = (V, E)

- V: alternatives to be ranked or rated
- $(i_{\alpha}, j_{\alpha}) \in E$ a pair of alternatives
- $y_{ii}^{\alpha} \in \mathbb{R}$ degree of preference by rater α
- $\omega_{ii}^{\alpha} \in \mathbb{R}_+$ confidence weight of rater α
- Examples: relative attributes, subjective QoE assessment, perception of illuminance intensity, sports, wine taste, etc.

Outline	Social Choice	Hodge Theory	Random Graphs	Game Theory

Modern settings

Modern ranking data are

- distributive on networks
- incomplete with missing values
- imbalanced
- even adaptive to dynamic and random settings?

Here we introduce:

Hodge Theory approach to Social Choice or Preference Aggregation

Outline	Social Choice	Hodge Theory	Random Graphs	Game Theory				
	•••••••••••							
Social Choice a	Social Choice and Impossibility Theorems							
Histor	у							

Classical social choice theory origins from Voting Theory

- Borda 1770, B. Count against plurality vote
- Condorcet 1785, C. Winner who wins all paired elections
- Impossibility theorems: Kenneth Arrow 1963, Amartya Sen 1973
- Resolving conflicts: *Kemeny*, *Saari* ...
- In these settings, we study complete ranking orders from voters.

Social Choice

Hodge Theory

Game Theory 00000000000

Social Choice and Impossibility Theorems

Classical Social Choice or Voting Theory

Problem

Given *m* voters whose preferences are total orders (permutation) $\{\succeq_i: i = 1, ..., m\}$ on a candidate set *V*, find a social choice mapping

$$f:(\succeq_1,\ldots,\succeq_m)\mapsto\succeq^*,$$

as a total order on V, which "best" represents voter's will.

Social Choice

э

Social Choice and Impossibility Theorems

Example: 3 candidates ABC

Preference order	Votes
$A \succeq B \succeq C$	2
$B \succeq A \succeq C$	3
$B \succeq C \succeq A$	1
$C \succeq B \succeq A$	3
$C \succeq A \succeq B$	2
$A \succeq C \succeq B$	2

Social Choice

Hodge Theory

Random Graphs

Game Theory 000000000000

Social Choice and Impossibility Theorems

What we did in practice I: Position rules

There are two important classes of social mapping in realities:

I. Position rules: assign a score s : V → ℝ, such that for each voter's order(permutation) σ_i ∈ S_n (i = 1,..., m), s_{σ_i(k)} ≥ s_{σ_i(k+1)}. Define the social order by the descending order of total score over raters, i.e. the score for k-th candidate

$$f(k) = \sum_{i=1}^m s_{\sigma_i}(k).$$

• Borda Count: $s: V \to \mathbb{R}$ is given by $(n-1, n-2, \dots, 1, 0)$

- Vote-for-top-1: (1,0,...,0)
- Vote-for-top-2: (1, 1, 0, ..., 0)

Game Theory

Social Choice and Impossibility Theorems

Social Choice

What we did in practice II: pairwise rules

- II. Pairwise rules: convert the voting profile, a (distribution) function on n! set S_n , into paired comparison matrix $X \in \mathbb{R}^{n \times n}$ where X(i, j) is the number (distribution) of voters that $i \succ j$; define the social order based on paired comparison data X.
 - Kemeny Optimization: minimizes the number of pairwise mismatches to X over S_n (NP-hard)
 - Pluarity: the number of wins in paired comparisons (tournaments) - equivalent to Borda count in complete Round-Robin tournaments

Social Choice

Hodge Theory 00000000000000000000 Random Graphs

Game Theory 000000000000

Social Choice and Impossibility Theorems

Revisit the ABC-Example

Preference order	Votes
$A \succeq B \succeq C$	2
$B \succeq A \succeq C$	3
$B \succeq C \succeq A$	1
$C \succeq B \succeq A$	3
$C \succeq A \succeq B$	2
$A \succeq C \succeq B$	2

Social Choice and Impossibility Theorems							
Voting	chaos!						

- Position:
 - s < 1/2, C wins
 - s = 1/2, ties
 - s > 1/2, A/B wins
- Pairwise:
 - A, B: 13 wins
 - C: 14 wins
 - Kemeny winner: C
- so completely in chaos!

Hodge Theory

Random Graphs

Game Theory 000000000000

Social Choice and Impossibility Theorems

Arrow's Impossibility Theorem

(Arrow'1963)

Consider the Unrestricted Domain, i.e. voters may have all complete and transitive preferences. The only social choice rule satisfying the following conditions is the dictator rule

- Pareto (Unanimity): if all voters agree that $A \succeq B$ then such a preference should appear in the social order
- Independence of Irrelevant Alternative (IIA): the social order of any pair only depends on voter's relative rankings of that pair

Hodge Theory

Random Graphs

Game Theory 000000000000

Social Choice and Impossibility Theorems

Sen's Impossibility Theorem

(Sen'1970)

With Unrestricted Domain, there are cases with voting data that no social choice mapping,

$$f:(\succeq_1,\ldots,\succeq_m)\mapsto 2^V,$$

exists under the following conditions

- Pareto: if all voters agree that A > B then such a preference should appear in the social order
- Minimal Liberalism: two distinct voters decide social orders of two distinct pairs respectively

Social Choice

Hodge Theory

Random Graphs

| 4 同 1 4 三 1 4 三 1

Game Theory 000000000000

Saari Decomposition

A Possibility: Saari's Profile Decomposition

Every voting profile, as distributions on symmetric group S_n , can be decomposed into the following components:

- Universal kernel: all ranking methods induce a complete tie on any subset of V
 - dimension: $n! 2^{n-1}(n-2) 2$
- Borda profile: all ranking methods give the same result
 - dimension: n-1
 - basis: $\{1(\sigma(1) = i, *) 1(*, \sigma(n) = i) : i = 1, ..., n\}$
- Condorcet profile: all positional rules give the same result
 dimension: (n-1)!/2
 - basis: sum of Z_n orbit of σ minus their reversals
- Departure profile: all pairwise rules give the same result

Social Choice

Hodge Theory

Random Graphs

Game Theory 000000000000

Saari Decomposition

Example: Decomposition of Voting Profile $R^{3!}$

Yuan Yao Applied Hodge Theory

Social Choice

Hodge Theory

Game Theory 00000000000

Saari Decomposition

Borda Count: the most consistent rule?

Table: Invariant subspaces of social rules (-)

	Borda Profile	Condorcet	Departure
Borda Count	consistent	-	-
Pairwise	consistent	inconsistent	-
Position (non-Borda)	consistent	-	inconsistent

- So, if you look for a best possibility from impossibility, Borda count is perhaps the choice
- Borda Count is the projection onto the Borda Profile subspace

Social Choice

Hodge Theory

Random Graphs

▲ □ ▶ ▲ □ ▶ ▲ □ ▶

Game Theory 00000000000

Saari Decomposition

Equivalently, Borda Count is a Least Square

Borda Count is equivalent to

$$\min_{\beta \in \mathbf{R}^{|V|}} \sum_{\alpha, \{i,j\} \in E} \omega_{ij}^{\alpha} (\beta_i - \beta_j - Y_{ij}^{\alpha})^2,$$

where

- E.g. $Y_{ij}^{\alpha} = 1$, if $i \succeq j$ by voter α , and $Y_{ij}^{\alpha} = -1$, on the opposite.
- Note: NP-hard (n > 3) Kemeny Optimization, or Minimimum-Feedback-Arc-Set:

$$\min_{s \in \mathrm{R}^{|V|}} \sum_{\alpha, \{i,j\} \in E} \omega_{ij}^{\alpha} (\operatorname{sign}(\beta_i - \beta_j) - \hat{Y}_{ij}^{\alpha})^2$$

Game Theory 000000000000

Hodge Decomposition

Why? Hodge Decomposition in Linear Algebra

For inner product spaces \mathcal{X} , \mathcal{Y} , and \mathcal{Z} , consider

$$\mathcal{X} \xrightarrow{A} \mathcal{Y} \xrightarrow{B} \mathcal{Z}.$$

and $\Delta = AA^* + B^*B : \mathcal{Y} \to \mathcal{Y}$ where $(\cdot)^*$ is adjoint operator of (\cdot) . If

 $B \circ A = 0$,

then $\ker(\Delta) = \ker(A^*) \cap \ker(B)$ and *orthogonal* decomposition

 $\mathcal{Y} = \operatorname{im}(A) + \operatorname{ker}(\Delta) + \operatorname{im}(B^*)$

Note: $\operatorname{ker}(B)/\operatorname{im}(A) \simeq \operatorname{ker}(\Delta)$ is the (real) (co)-homology group $(\mathbb{R} \to \operatorname{rings}; \operatorname{vector spaces} \to \operatorname{module}).$

Outline	Social Choice 00000000000000	Hodge Theory 00●0000000000000000000000000000000000	Random Graphs 00000000	Game Theory 000000000000

- Homology: $\mathcal{X} = C_2(\chi_C, \mathcal{Z}), \mathcal{Y} = C_1(\chi_C, \mathcal{Z})$, and $\mathcal{Z} = C_0(\chi_G, \mathcal{Z}),$ • boundary map: $\partial_2 : C_2(\chi_G) \to C_1(\chi_G)$ by $\partial_2(e_{iik}) = e_{ii} + e_{ik} + e_{ki}$ with $e_{st} = -e_{ts}$; $\partial_1: C_1(\chi_G) \to C_0(\chi_G)$ defined by $\partial_1(e_{ii}) = e_i - e_i$ • Closedness: $\partial_1 \circ \partial_2 = 0$ • Homology group: $H_1(\chi_G, \mathcal{Z}) = \ker(\partial_1) / \operatorname{im}(\partial_2)$ • Cohomology: $\mathcal{X} = C^0(\chi_C, \mathbb{R}), \ \mathcal{Y} = C^1(\chi_C, \mathbb{R})$, and $\mathcal{Z} = C^2(\chi_C, \mathbb{R}).$ • coboundary map: $\delta_0 : C^0 \to C^1$ by $(\delta_0 f)(i, j) = f_i - f_i$; $\delta_1: C^1 \to C^2$ by $(\delta_1 g)(i, j, k) = g_{ii} + g_{ik} + g_{ki}$ • Closedness: $\delta_1 \circ \delta_0 = 0$
 - Co-homology group: $H^1(\chi_{\mathcal{G}},\mathbb{R}) = \ker(\delta_1)/\operatorname{im}(\delta_0)$

Outline	Social Choice	Hodge Theory	
		000000000000000000000000000000000000000	

Game Theory

Hodge Decomposition

Hodge Decomposition=Rank-Nullity Theorem

Take product space $V = \mathcal{X} \times \mathcal{Y} \times \mathcal{Z}$, define

$$D = \begin{pmatrix} 0 & 0 & 0 \\ A & 0 & 0 \\ 0 & B & 0 \end{pmatrix}, \quad BA = 0,$$

Rank-nullity Theorem: $im(D) + ker(D^*) = V$, in particular

$$\mathcal{Y} = \operatorname{im}(A) + \operatorname{ker}(A^*) = \operatorname{im}(A) + \operatorname{ker}(A^*) / \operatorname{im}(B^*) + \operatorname{im}(B^*), \text{ since } \operatorname{im}(A) \subseteq \operatorname{ker}(B) = \operatorname{im}(A) + \operatorname{ker}(A^*) \cap \operatorname{ker}(B) + \operatorname{im}(B^*)$$

Laplacian

$$L = (D+D^*)^2 = \mathsf{diag}(A^*A, AA^*+B^*B, BB^*) = \mathsf{diag}(L_0, L_1, L_2^{(down)})$$

Outline	Social Choice 00000000000000	Hodge Theory 0000€00000000000000000000000000000000	Random Graphs 000000000	Game Theory 000000000000
Hodge Decompos	sition			
Hence,	in our case			

Note $B \circ A = 0$ since

$$(B \circ Ax)(i, j, k) = (x_i - x_j) + (x_j - x_k) + (x_k - x_i) = 0.$$

Hence

$$A^{T}\hat{y} = A^{T}(Ax + B^{T}z + w) = A^{T}Ax \Rightarrow x = (A^{T}A)^{\dagger}A^{T}\hat{y}$$
$$B\hat{y} = B(Ax + B^{T}z + w) = BB^{T}z \Rightarrow z = (BB^{T})^{\dagger}B\hat{y}$$
$$A^{T}w = Bw = 0 \Rightarrow w \in \ker(\Delta_{1}), \quad \Delta_{1} = AA^{T} + B^{T}B.$$

Game Theory 000000000000

Combinatorial Hodge Theory on Simplicial Complexes

Example: graph and clique complex

- G = (X, E) is a undirected but oriented graph
- Clique complex $\chi_G \subseteq 2^X$ collects all complete subgraph of G
- k-forms or cochains $\Omega^k(\chi_G)$ as alternating functions:
 - 0-forms: $v: V \to \mathbb{R} \cong \mathbb{R}^n$
 - 1-forms as skew-symmetric functions: $w_{ij} = -w_{ji}$
 - 2-forms as triangular-curl:

$$z_{ijk} = z_{jki} = z_{kij} = -z_{jik} = -z_{ikj} = -z_{kji}$$

coboundary operators as alternating difference operators:

•
$$(d_0v)(i,j) = v_j - v_i =: (\text{grad } v)(i,j)$$

• $(d_1w)(i,j,k) = (\pm)(w_{ij} + w_{jk} + w_{ki}) =: (\operatorname{curl} w)(i,j,k)$

 $\bullet d_1 \circ d_0 = \operatorname{curl}(\operatorname{grad} u) = 0$

- combinatorial Laplacian $\Delta = d_{k-1}d_{k-1}^* + d_k^*d_k$
 - k = 0, $\Delta_0 = d_0^* d_0$ is the (unnormalized) graph Laplacian
 - k = 1, 1-Hodge Laplacian (Helmholtzian)

 $\Delta_1 = \mathsf{curl} \circ \mathsf{curl}^* - \mathsf{div} \circ \mathsf{grad}$

Hodge decomposition holds for Ω^k(X)
 Ω^k(X) = im(d_{k-1}) ⊕ ker(Δ_k) ⊕ im(δ_k)
 dim(ker(Δ_k)) = β_k(χ(X)), k-harmonics

Condorcet Profile in Harmonic Ranking

ŷ^(h) = w, the global inconsistency, harmonic ranking (Z_n-invariant)

$$\hat{y}_{ij}^{(h)} + \hat{y}_{jk}^{(h)} + \hat{y}_{ki}^{(h)} = 0, \text{ for each } \{i, j, k\} \in T,$$
 (3a)
 $\sum_{j \sim i} \omega_{ij} \hat{y}_{ij}^{(h)} = 0, \text{ for each } i \in V.$ (3b)

• voting chaos: circular coordinates on $V \Rightarrow$ fixed tournament issue

Cyclic Ranking and Outliers: High Dimensional Statistics

 Outliers are sparse approximation of cyclic rankings (curl+harmonic) [Xu-Xiong-Huang-Y.'13]

$$\min_{\gamma} \|\Pi_{\ker(A^*)}(\hat{y} - \gamma)\|^2 + \lambda \|\gamma\|_1$$

Robust ranking can be formulated as a Huber's LASSO

$$\min_{x,\gamma} \|\hat{y} - Ax - \gamma\|^2 + \lambda \|\gamma\|_1$$

- outlier γ is incidental parameter (Neyman-Scott'1948)
- global rating x is structural parameter
- Yet, LASSO is a biased estimator (Fan-Li'2001)

 A Dual Gradient Descent (sparse mirror descent) dynamics [Osher-Ruan-Xiong-Y.-Yin'2014, Huang-Sun-Xiong-Y.'2020]

$$\dot{\rho}_t = \frac{1}{n} X^T (y - X \beta_t), \qquad (4a)$$

$$\rho_t \in \partial \|\beta_t\|_1. \tag{4b}$$

- called Inverse Scale Space dynamics in imaging
- sign consistency under nearly the same conditions as LASSO (Wainwright'99), yet returns unbiased estimator
- fast and scalable discretization as linearized Bregman Iteration

From Social Choice to Personalized Ranking

Conflicts are due to personalization [Xu-...-Y.'2019]

cycles = personalized ranking + position bias + noise.

Linear mixed-effects model for annotator's pairwise ranking:

$$y_{ij}^{u} = (\theta_i + \frac{\delta_i^{u}}{\delta_i}) - (\theta_j + \frac{\delta_j^{u}}{\delta_j}) + \gamma^{u} + \varepsilon_{ij}^{u},$$
(5)

where

Outline

- θ_i is the common global ranking score, as a fixed effect;
- δ_i^u is the annotator's preference deviation from the common ranking θ_i such that $\theta_i^u := \theta_i + \delta_i^u$ is u's personalized ranking;
- γ^u is an annotator's position bias, which captures the careless behavior by clicking one side during the comparisons;
- ε_{ij}^{u} is the random noise which is assumed to be independent and identically distributed with zero mean and being bounded.

From Social Choice to Personalized Ranking

Topological Obstructions

Two topological conditions are important:

- Connectivity:
 - G is connected \Rightarrow unique global ranking is possible;
- Loop-free:

• for cyclic rankings, consider clique complex $\chi^2_G = (V, E, T)$ by attaching triangles $T = \{(i, j, k)\}$

• dim(ker(Δ_1)) = $\beta_1(\chi_G^2)$, so harmonic ranking w = 0 if χ_G^2 is loop-free, here topology plays a role of obstruction of fixed-tournament

• "Triangular arbitrage-free implies arbitrage-free"

Phase Transitions in Topology

Random Graph Models for Crowdsourcing

- Recall that in crowdsourcing ranking on internet,
 - unspecified raters compare item pairs randomly
 - online, or sequentially sampling
- random graph models for experimental designs
 - *P* a distribution on random graphs, invariant under permutations (relabeling)
 - Generalized de Finetti's Theorem [Aldous 1983, Kallenberg 2005]: P(i,j) (*P* ergodic) is an uniform mixture of

$$h(u, v) = h(v, u) : [0, 1]^2 \to [0, 1],$$

h unique up to sets of zero-measure

- Erdös-Rényi: $P(i,j) = P(edge) = \int_0^1 \int_0^1 h(u,v) du dv =: p$
- edge-independent process (Chung-Lu'06)

Phase Transitions in Topology

Phase Transitions of Large Random Graphs

For an Erdos-Renyi random graph G(n, p) with *n* vertices and each edge independently emerging with probability p(n),

- (Erdös-Rényi 1959) One phase-transition for β_0
 - $p << 1/n^{1+\epsilon}~(orall \epsilon > 0)$, almost always disconnected
 - p >> log(n)/n, almost always connected
- (Kahle 2009) Two phase-transitions for β_k (k ≥ 1)
 p << n^{-1/k} or p >> n^{-1/(k+1)}, almost always β_k vanishes;
 - p << n of p >> n of p >> n of p >> n.

For example: with n = 16, 75% distinct edges included in G, then χ_G with high probability is connected and loop-free. In general, $O(n \log(n))$ samples for connectivity and $O(n^{3/2})$ for loop-free.

Random Graphs

Game Theory 00000000000

Phase Transitions in Topology

Three sampling methods

- Uniform sampling with replacement (i.i.d.) (G₀(n, m)).
 Each edge is sampled from the uniform distribution on ⁿ₂ edges, with replacement. This is a weighted graph and the sum of weights is m.
- Uniform sampling without replacement (G(n, m)).
 - Each edge is sampled from the uniform distribution on the available edges without replacement. For $m \leq \binom{n}{2}$, this is an instance of the Erdös-Rényi random graph model G(n, p) with $p = m/\binom{n}{2}$.

• Greedy sampling $(G_*(n, m))$.

• Each pair is sampled to maximize the algebraic connectivity of the graph in a greedy way: the graph is built iteratively; at each iteration, the Fiedler vector is computed and the edge (i, j) which maximizes $(\psi_i - \psi_j)^2$ is added to the graph.

Fiedler Value Asymptotics

Asymptotic Estimates for Fiedler Values [Braxton-Xu-Xiong-Y., ACHA16]

Key Estimates of Fiedler Value near Connectivity Threshold.

$$G_{0}(n,m): \quad \frac{\lambda_{2}}{np} \approx a_{1}(p_{0},n) := 1 - \sqrt{\frac{2}{p_{0}}}\sqrt{1 - \frac{2}{n}}$$
(6)
$$G(n,m): \quad \frac{\lambda_{2}}{np} \approx a_{2}(p_{0},n) := 1 - \sqrt{\frac{2}{p_{0}}}\sqrt{1 - p}$$
(7)

where $p_0 := 2m/(n\log n) \ge 1$, $p = \frac{p_0\log n}{n}$ and

$$a(p_0) = 1 - \sqrt{2/p_0} + O(1/p_0), \quad ext{ for } p_0 \gg 1.$$

Game Theory: Multiple Utilities

Multiple Utility Flows for Games

Extension to multiplayer games: G = (V, E)

- $V = \{(x_1, ..., x_n) =: (x_i, x_{-i})\} = \prod_{i=1}^n S_i$, *n* person game;
- undirected edge: $\{(x_i, x_{-i}), (x'_i, x_{-i})\} = E$
- each player has utility function $u_i(x_i, x_{-i})$;
- Edge flow (1-form): $u_i(x_i, x_{-i}) u_i(x'_i, x_{-i})$

Social Choice

Hodge Theory

Random Graphs

Game Theory

Game Theory: Multiple Utilities

Nash and Correlated Equilibrium

 $\pi(x_i, x_{-i})$, a joint distribution tensor on $\prod_i S_i$, satisfies $\forall x_i, x'_i$,

$$\sum_{x_{-i}} \pi(x_i, x_{-i})(u_i(x_i, x_{-i}) - u_i(x'_i, x_{-i})) \ge 0,$$

- i.e. expected flow $(\mathbb{E}[\cdot|x_i])$ is nonnegative. Then,
 - tensor π is a correlated equilibrium (CE, Aumann 1974);
 - if π is a rank-one tensor,

$$\pi(\mathbf{x})=\prod_i\mu(\mathbf{x}_i),$$

then it is a Nash equilibrium (NE, Nash 1951);

- pure Nash-equilibria are sinks;
- fully decided by the edge flow data.

< □ > < 同 >

▲ □ ▶ ▲ □ ▶ ▲

Game Theory: Multiple Utilities

What is a correct notion of Equilibrium?

- Players are never independent in reality, e.g. Bayesian decision process (Aumman'87)
- Finding NE is NP-hard, e.g. solving polynomial equations (Sturmfels'02, Datta'03)
- Finding CE is linear programming, easy for graphical games (Papadimitriou-Roughgarden'08)
- Some natural learning processes (best-response) converges to CE (Foster-Vohra'97)

Random Graphs

Game Theory

Game Theory: Multiple Utilities

Another simplification: Graphical Games

- *n*-players live on a network of *n*-nodes
- player *i* utility only depends on its neighbor players N(*i*) strategies
- correlated equilibria allows a concise representation with parameters linear to the size of the network (Kearns et al. 2001; 2003)

$$\pi(x) = \frac{1}{Z} \prod_{i=1}^{n} \psi_i(x_{N(i)})$$

- this is not rank-one, but low-order interaction
- reduce the complexity from $O(e^{2^n})$ to $O(ne^{2^d})$

$$(d = \max_i |N(i)|)$$

• polynomial algorithms for CE in tree and chodal graphs.

Hodge Decomposition of Finite Games

Hodge Decomposition of Finite Games

Theorem (Candogan-Menache-Ozdaglar-Parrilo,2011)

Every finite game admits a unique decomposition:

Potential Games \oplus Harmonic Games \oplus Neutral Games

Furthermore:

- Shapley-Monderer Condition: Potential games ≡ quadrangular-curl free
- Extending G = (V, E) to complex by adding quadrangular cells, harmonic games can be further decomposed into (quadrangular) curl games

Outline	Social Choice 00000000000000	Hodge Theory 0000000000000000000	Random Graphs 000000000	Game Theory ○○○○○○●○○○○○		
Hodge Decomposition of Finite Games						
Bimatr	ix Games					

For bi-matrix game (A, B),

- potential game is decided by ((A + A')/2, (B + B')/2)
- harmonic game is zero-sum ((A A')/2, (B B')/2)
- Computation of Nash Equilibrium:
 - each of them is tractable
 - however direct sum is NP-hard
 - approximate potential game leads to approximate NE

Hodge Decomposition of Finite Games

Example: Hodge Decomposition of Prisoner's Dilemma

- · Every game can be mapped to a flow preserving its Nash equilibrium
- Game flow = potential + harmonic

STRATEGIE S	B Cooperate	B Defect
A Cooperate	(3,3)	(0,5)
A Defect	(5,0)	(1,1)

Note: Prisoner's dilemma is a potential game to its Nash equilibrium, not efficient! So we want new way for flow construction...

Candogan-Menache-Ozdaglar-Parrilo, 2010, Flows and Decompositions of Games: Harmonic and Potential Games, arXiv: 1004.2405v1, May 13, 2010.

Note: Shapley-Monderer Condition \equiv Harmonic-free \equiv quadrangular-curl free
